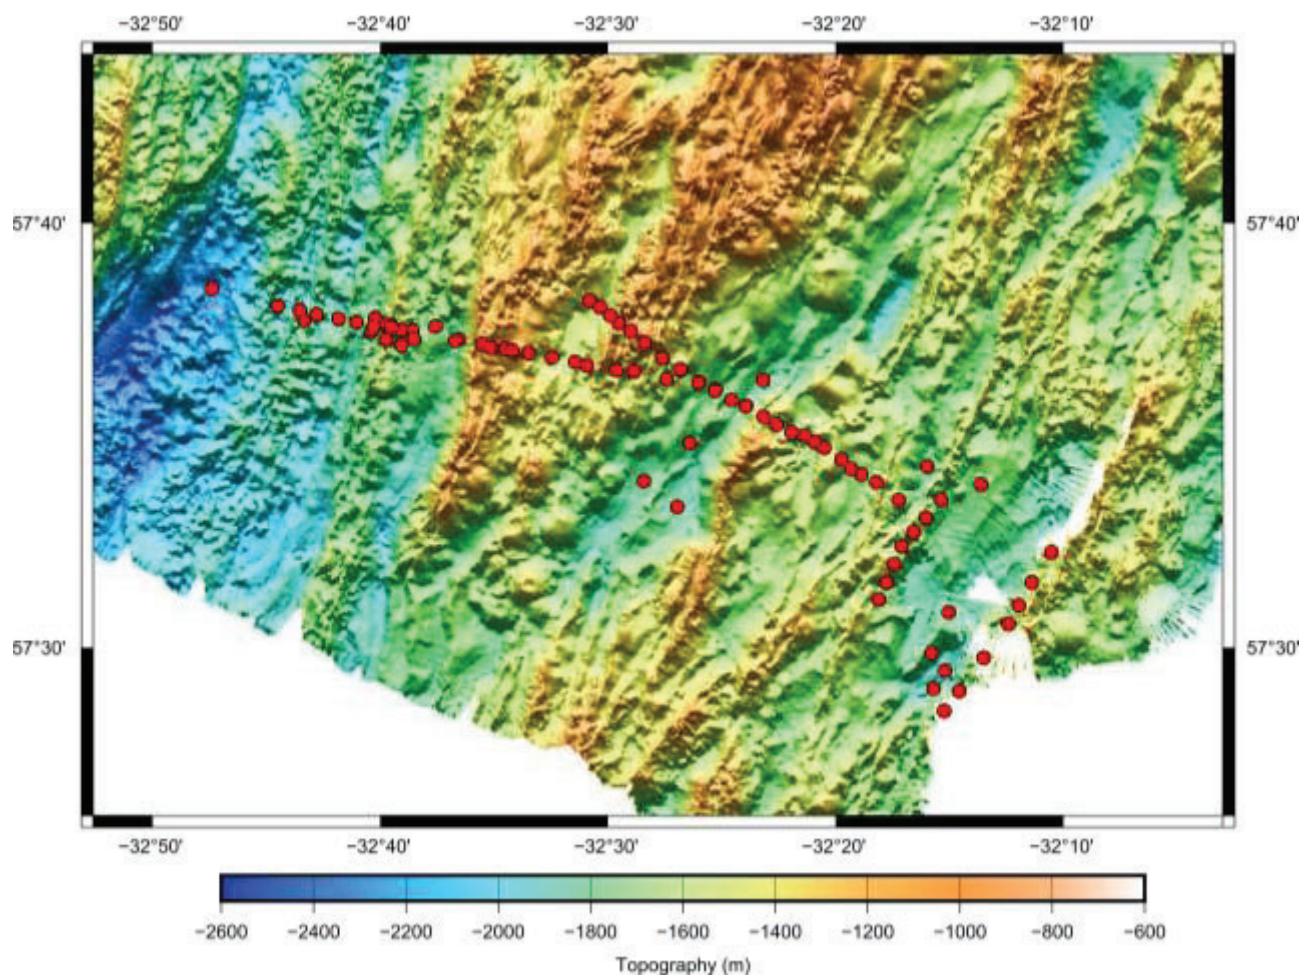

Fig. 2: stations of R/V MARIA S. MERIAN cruise MSM119.

## Objectives

The research cruise MSM119, also known as RIFLOR-2, set out to further investigate sedimentary ponds and crustal ridges along the eastern flank of the southernmost tip of the Reykjanes Ridge, Mid-Atlantic Ridge. Based on site-survey work during cruise M183 (2022) with RV METEOR, the MARUM MeBo70 seafloor drill rig represented the main work horse on expedition MSM119. In general, the research focuses on the relevance of hydrothermal circulation in the flanks of oceanic ridges, and in particular of young basaltic crust with low sediment cover on the Reykjanes Ridge south of Iceland. The global importance of these circulation systems for the exchange between the crust and the oceans as well as the deep biosphere and their role in the carbon cycle will be assessed by drilling, sampling and monitoring locations of seawater inflow and outflow in cool and warm regions along a transect from the spreading ridge axis to the ca. 3 Ma old Squid Pond. The post-cruise work will take place in the context of the MARUM Cluster of Excellence "Ocean Floor" and the DAM research mission "CDRmare" (project AIMS<sup>3</sup>).

The main results of cruise MSM119 include:

- Successful installation of 4 MeBo borehole observatories in a total of 9 holes drilled in 1.500 – 1.700 meters of water depth, with a total penetration of 242 meters below seafloor and an average core recovery of 44%;
- Recovery of 19 gravity cores to characterise sediment in the recharge and discharge ends of Squid Pond and along a transect of very young (ca. 0.1 Ma) to ca. 3 Ma old crust on the Reykjanes Ridge;
- 89 deployments of a T gradient lance;
- Multibeam mapping of a wide area from spreading ridge axis to the Squid Pond at the southern Reykjanes Ridge (RR), including some selected ParaSound profiling along the transects we samples with gravity core and T-lance;
- 5 dredges taken along strike of the RR axis to sample distinct age segments for basaltic crust and other rocks outcropping;
- (Short-term) deployment of the MARUM *develogic* seafloor lander to monitor bottom water composition at a potential discharge site.

## Narrative

Cruise MSM119 started in the morning of July 8, 2023 in St. John's, Newfoundland, Canada. After a 4-day ENE-ward transit, the vessel arrived in the working area on the Mid-Atlantic Ridge early on July 12, 2023. Station work on the southern Reykjanes Ridge started with VSP for calibration of the hydroacoustic systems. The station work initially served to explore a small sediment trough on the eastern flank of the ridge. In the so-called Squid Pond we recorded a velocity sound profile and recorded hydroacoustic data before using gravity corers and in situ temperature lances to collect material and data where our understanding was still incomplete after the preliminary investigations during the METEOR cruise M183 in 2022. Both methods have been used primarily on the eastern side of the sediment trough, where cold seawater is charged into the seafloor and continues to circulate westward through the crust, being heated and expelled as hydrothermal fluid again. Changes in oxygen and alkalinity confirm this fluid movement.

Over the weekend, the MARUM MeBo70 drilling rig was used for the first time on the seabed for a pilot drilling in the Squid Pond. After a good 24m of sediment cover, we encountered ocean crust material and had to drill carefully with slow drilling progress. Some pieces of basalt blocked the core barrel at the end of the drilling, as we were able to determine on deck after successfully recovering the drill.

In the week from the 17<sup>th</sup> to the 23<sup>rd</sup> of July we successfully continued the multi-methodological research program on the Reykjanes Ridge with consistently good weather conditions. The deployment of equipment included hydroacoustic data acquisition with Multibeam and Parasound, gravity coring, measurements with an in-situ temperature lance, drilling with MARUM MeBo70, and deployment and recovery of a dredge.

Our second drilling with MeBo aimed to completely core the sediments of the Squid Pond near the spreading axis, to take in-situ temperature measurements at intervals of about 5 meters, and then to log the complete sediment sequence with an acoustic borehole tool. The borehole reached into the oceanic crust and cored very solid, cemented sandstones at the transition to the sediment filling, which were probably formed by precipitated solutions from the upper crust.

The periods between the MeBo missions are used to connect the spreading axis with the Squid Pond with a transect of heavy corers and temperature measurements and to better characterize the ridge flank processes. In the considered time slice of the earth's history, i.e. the last 3 million years, we see thermal variability in the data, differently consolidated and

altered sediments, variable pore water compositions, and different proportions of magmatic components. However, only analyzes in the home laboratories will allow conclusions to be drawn as to the extent to which this material comes from the dorsal axis or, for example, from Iceland. In order to trace different magma compositions or changes in the rock-physical properties of the oceanic crustal basalts, complementary short dredge trains are run parallel to crustal age isolines. Initial response shows that fresh or superficially altered basalts are dominant, and more rarely blistered varieties are found. Occasionally, other lithologies were found and are interpreted to represent glacial drop stones.

In the week from the 31<sup>st</sup> to the 6<sup>th</sup> of August we had good weather conditions without exception, which we mainly used for three boreholes with the MARUM MeBo70. The gravity corer and dredge as well as the in-situ temperature lance were used between the deployments of the seabed drilling robot.

In total, we managed to drill three boreholes through overburden sediments into the oceanic crustal basalts in the past week. Two of the drill holes were drilled in pairs on a relatively young portion of the ocean ridge flank approximately 80 meters apart. The chemistry of the crustal fluids and the temperature changes deep in the borehole are to be recorded over a period of two years. A third hole was completed in Squid Pond where the ridge is slightly older. This borehole was also fitted with an osmo-sampler observatory and is thus used to record a geochemical time series. Scientific work during that week also encompassed gravity coring, T-gradient measurements and dredging.

During our final working week, a fourth observatory deployment in another MeBo hole at Squid Pond got equipped with a simple T-CORK fabricated on board. There we installed one of only 3 MTLs left from the earlier measurements in the vicinity of the Reykjanes Ridge axis. The final station on August 7 was then a system test of the MARUM seafloor lander, which ascended to the calm Atlantic Ocean in moonshine and with Northern lights over clear skies.

On August 8, 2023 station work ended at 1:26 UTC and R/V MARIA S. MERIAN started its transit back to St. John's, Newfoundland, Canada. There, the cruise ended on August 12, 2023 at 8:36h in the morning with all scientists preparing for departure and MeBo demobilisation.

## Acknowledgements

We thank Master Björn Maass and his team on the bridge for their cooperation, and outstanding support during complex operations, partly in heavy weather. Special thanks go also to bosun Plinki and the entire crew of R/V MARIA S. MERIAN for their friendly and professional support and efficient technical assistance with the MeBo70 drill rig and other devices used. Plinki is particularly thanked for tremendous extra efforts at the end of the cruise where he provided the T-CORK observatory and made the observatory part of the cruise a major success.

Colleagues at MARUM Bremen (Vera Bender, Marco Klann, Goetz Ruhland) have also provided crucial help with expedition planning, logistical decisions, and post-cruise demobilisation.

Thanks go also to the German Science Foundation (DFG), the German Federal Ministry for Education and Research (BMBF) and the European Research Council for providing the funds to realize cruise MSM119 with large seagoing gear and costly long-term monitoring technology. Funding was explicitly received through MARUM Cluster of Excellence “The Ocean Floor” (grant EXC2077), AIMS<sup>3</sup> within DAM CDRmare (BMBF grant 03F0894), and ERC Synergy project T-Sector (grant ERC-2022-SYG #101071713).

## **Participants list**

Achim Kopf (MARUM), Chief scientist  
Emilia Athanasiadis (Univ. Bremen), Hydroacoustics  
Markus Bergenthal (MARUM), MeBo  
Renée Bernhard (Univ. Bremen), Temperature measurements, Log book  
Denise Bethke (AWI), PW and gas chemistry  
Ousmane Coulibaly (MARUM), MeBo

## Station list

GeoB Nr.: Curation number of the MARUM core repository

Gear Abbreviations: SBE/ParaS = Ship-mounted Multibeam/Parasound; XSV = expendable sound velocimeter; GC = Gravity Corer; DREDGE = Chain-bag Dredge; CTD = Conductivity-temperature-density sensor; MeBo = MeBo deployment; Lander = Lander deployment; TL = Temperature Lance.

NOTE: Date/Time/Latitude/Longitude/Water Depth are relative to either the start and end of the operation (SBE/ParaS, XSV, DREDGE, CTD) or the time at which the gear reaches the seafloor (GC, MeBo, TL, Lander).
